Abstract- *High-performance concrete is defined as concrete that meets special combinations of performance and uniformity requirements that cannot always be achieved routinely using conventional constituents and normal mixing, placing, and curing practices. Ever since the term high-performance concrete was introduced into the industry, it had widely used in large- scale concrete construction that demands high strength, high flow ability, and high durability. A high-strength concrete is always a high-performance concrete, but a high-performance concrete is not always a high-strength concrete. Durable concrete specifying a high-strength concrete does not ensure that a durable concrete will be achieved. It is very difficult to get a product which simultaneously fulfills all of the properties. So the different pozzolanic materials like Ground Granulated Blast furnace Slag (GGBS), Silica Fume, Rice Husk Ash, Fly Ash, High Reactive Metakaolin, are some of the pozzolanic materials which can be used in concrete as partial replacement of cement, which are very essential ingredients to produce high performance concrete. It is very important to maintain the water cement ratio within the minimal range, for that we have to use the water reducing admixture i.e. superplasticizer, which plays an important role for the production of high performance concrete. So I herein this project will test on different materials like Ground Granulated Blast Furnace Slag, and Silica Fume to obtain the desired needs. I will use synthetic fiber (i.e. Recron fiber) in percentage 0.2%, 0.3%, 0.4% to that of total weight of composite and casting will be done to find out the optimum percentage of fiber to be used. Finally I will use different percentage of Silica Fume & GGBS with the replacement of cement keeping constant the optimum fiber content and concrete will be casted. Compressive test, splitting test, flexural test will be conducted on the prepared mortar cubes, cylinders & prisms.*

Keywords- Recron Fiber, Silica Fume, GGBFS, Strength Test.

I. INTRODUCTION

Concrete is the most widely used man-made construction material in the world. It is obtained by mixing cementitious materials, water, aggregate and sometimes admixtures in required proportions. The utility and elegance as well as the durability of concrete structures, built during the first half of the last century with Ordinary Portland Cement

(OPC) and plain round bars of mild steel, the easy availability of the constituent materials of concrete and the knowledge that virtually any combination of the constituents leads to a mass of concrete have bred contempt. Strength was emphasized without a thought on the durability of structures. As a consequence of the liberties taken, the durability of concrete and concrete structures is on a southward journey; a journey that seems to have gained momentum on its path to self-destruction. The Ordinary Portland Cement (OPC) is one of the main ingredients used for the production of concrete and has no alternative in the civil construction industry. Unfortunately, production of cement involves emission of large amounts of carbon-dioxide gas into the atmosphere, a major contributor for green house effect and the global warming, hence it is inevitable either to search for another material or partly replace it by some other material. The search for any such material, which can be used as an alternative or as a supplementary for cement should lead to global sustainable development and lowest possible environmental impact. So for this we need to go for the addition of pozzolanic materials along with superplasticizer with having low water cement ratio. Also now a day's one of the great application in various structural field is fiber reinforced concrete, which is getting popularity because of its positive effect on various properties of concrete. The major advantages of fiber reinforced concrete are resistance to microcracking, impact resistance, resistance to fatigue, reduced permeability, and improved strength in shear, tension, flexure and compression.

II. OBJECTIVE OF THE STUDY

The objective of the present work is to develop concrete with good strength so that durability will be attained. So for the present work, use of different pozzolanic materials like ground granulated blast furnace slag, and silica fume along with fiber is made. The experimental program undertaken is as follow;

- a. To determine the mix proportion with ground granulated blast furnace slag and silica fume with fiber to achieve the desire needs.
- b. To determine the optimum percentage of fiber that can be added to concrete to achieve desired needs.

- c. Also to determine the optimum percentage of GGBFS and Silica Fume that can be replaced with cement in Fiber Reinforced Concrete.
- d. To investigate different basic properties of concrete such as compressive strength, splitting tensile strength, flexural strength.

III. MATERIAL PROPERTIES

3.1 Cement

Table No.1: Properties of Cement

Properties	Results
Grade	53 grade OPC
Initial Setting Time	131 min
Final Setting Time	315 min
Normal Consistency	31%
Specific Gravity	3.15
Specific Surface	330m ² /kg

3.2 Fine Aggregates

Table No.2: Properties of F.A

Properties	Results
Specific Gravity	2.59
Water Absorption	1.42%

3.3 Coarse aggregate

Table No.3: Properties of C.A

Properties	Results	
	20mm	12mm
Specific Gravity	2.78	2.75
Water Absorption	0.46%	0.52%

3.4 Mix Design

Table No.4: Mix Design

Grade Of Concrete	M30
Cementitious material	245kg/m ³
GGBS (@ 30% replacement of cement)	105 kg/m ³
Coarse aggregate : 20mm	794 kg/m ³
Coarse aggregate : 12mm	524 kg/m ³
Fine aggregate	693 kg/m ³
Water	140 kg/m ³
Superplasticizer(Sunplast @ 0.6 %)	2.1 kg/m ³
Fiber (Recron 3s Fiber @ 0.2 % of composite)	5.06 kg/m ³

IV. EXPERIMENTAL INVESTIGATION

1. Synthetic fiber i.e. Recron fiber is used in concrete for the production of fiber reinforced concrete. Recron fiber has been used in percentages i.e. 0.2%, 0.3%, and 0.4% to the weight of concrete and study the 7 days and 28 days compressive strength.
2. Out of 0.2%, 0.3%, and 0.4% addition of Recron fiber optimum percentage addition of Recron fiber is used for further study.
3. Different percentages of silica fume i.e. 5%, 10%, 15%, 20% and fixing constant fiber percentage at optimum percentage i.e. at 0.3% cubes, cylinders and prisms were casted and tested to analyze the change in compressive, splitting tensile and flexural strength.
4. GGBS at different percentage i.e. 30%, 40%, 50%, 60% and fixing constant fiber percentage at optimum percentage i.e. at 0.3% cubes, cylinders and prisms were casted and tested to analyze the change in compressive, splitting tensile and flexural strength.

V. TEST RESULTS

Table No.5: Effect of Recron fibre on compressive strength

Age of Cubes	% of Recron Fiber used		
	0.2%	0.3%	0.4%
7 days	23.76	26.89	25.05
28 days	37.86	39.65	38.20

From the above result it was observed that using Recron fiber from 0.2% to 0.4% the compressive strength is maximum at 0.3%, i.e. from 0.2% to 0.3% compressive strength was increased and on further increment of fiber content the strength reduces. The 7 day and 28 days compressive strength of concrete is higher at with 0.3% fiber compared to other fiber composition. So the optimum dosage of fiber for getting maximum strength for OPC is 0.3%.

Table no.6: Effect of GGBS on compressive strength using 0.3% fiber

GGBS (%)	7 days Compressive strength (N/mm ²)	28days compressive strength (N/mm ²)
0%	26.89	39.65
30%	26.97	39.98
40%	28.25	40.55
50%	31.45	42.55
60%	30.63	41.97

GGBS cement is added to concrete in the concrete manufacturer's batching plant, along with Portland cement, aggregates and water. GGBS is used as a direct replacement for Portland cement, on a one-to-one basis by weight. Replacement levels for GGBS vary from 30% to up to 85%. Typically 40 to 60% is used in most instances. In the study it was observed that cement when replaced with GGBS there is a considerable increase in compressive strength. Out of the four combinations considered cement replaced with 50% GGBFS shows higher strength and produced more workable concrete. In the 28 day strength there is an increase in strength for all the four combinations considered. Replacing cement with 50% GGBFS was considered as the optimum cement replacement for M30 concrete.

Table no. 7 Effect of GGBS on Split Tensile strength using 0.3% fiber

GGBS (%)	7 days Split Tensile strength (N/mm ²)	28days Split Tensile strength (N/mm ²)
0%	2.85	3.15
30%	2.92	3.26
40%	3.28	3.47
50%	3.44	3.68
60%	3.10	3.35

From the above result it is observed that as the replacement level increases there is an increase in split tensile strength for M30 grade of concrete up to 50% replacement level, and beyond that level there is a decrease in split tensile strength.

Table no. 8 Effect of GGBS on Flexural strength using 0.3% fiber

GGBS (%)	7 days Flexural strength (N/mm ²)	28days Flexural strength (N/mm ²)
0%	5.14	5.53
30%	5.21	5.79
40%	5.74	6.52
50%	6.36	6.89
60%	6.11	6.53

From the above observation it is clear that the flexural strength at the age of 28 days of GGBFS concrete continuously increased and reached a maximum value of 10% replacement level for M30 grade concrete respectively.

Table no. 9 Effect of Silica Fume on compressive strength using 0.3% fiber

GGBS (%)	7 days Compressive strength (N/mm ²)	28days compressive strength (N/mm ²)
0%	26.89	39.65
5%	31.07	42.78
10%	33.49	44.52
15%	31.19	43.88
20%	29.78	43.18

There is a significant improvement in the strength of concrete because of the high pozzolanic nature of the silica fume and its void filling ability. The compressive strength of the M30 mix at 7 and 28 days age, with replacement of cement by silica fume with 0.3% fiber content was increased gradually up to an optimum replacement level of 10% and then decreased. Cement replacement up to 10% with silica fume with a constant fiber content leads to increase in compressive strength.

Table no. 10 Effect of Silica Fume on Split Tensile strength using 0.3% fiber

GGBS (%)	7 days Split Tensile strength (N/mm ²)	28days Split Tensile strength (N/mm ²)
0%	2.85	3.15
5%	2.90	3.42
10%	3.31	4.07
15%	2.97	3.91
20%	2.82	3.75

As replacement level increases there is an increase in split tensile strength for M30 grade of concrete up to 10% replacement level, and beyond that level there is a decrease in split tensile strength.

Table no. 11 Effect of Silica Fume on Flexural strength strength using 0.3% fiber

GGBS (%)	7 days Flexural strength (N/mm ²)	28days Flexural strength (N/mm ²)
0%	5.14	5.53
5%	5.20	5.77
10%	5.71	6.24
15%	5.47	6.05
20%	5.17	5.88

The flexural strength at the age of 28 days of silica fume concrete continuously increased with respect to controlled concrete and reached a maximum value of 10% replacement level for M30 grade concrete respectively.

VI. CONCLUSION

1. Use of GGBS as cement replacement increases consistency.
2. Cement replaced with 50% GGBS with 0.3 % fiber shows higher compressive.
3. As the replacement level of cement by GGBS increases there is an increase in split tensile strength & flexural strength for M30 grade of concrete up to 50% replacement level, and beyond that level there is a decrease in split tensile and flexural strength.
4. Using 50% GGBS with 0.3% fiber percentage the 28 days compressive strength increases 7% more than concrete with 0.3% fiber only.
5. So it is inculcated that 0.3% Recron fibre and replacement of 50 % GGBS with cement is required to achieve desired needs.
6. As the replacement of cement with different percentages with Silica fume increases the consistency increases.
7. The compressive strength of the M30 mix at 7 and 28 days age, with replacement of cement by silica fume with 0.3% fiber content was increased gradually up to an optimum replacement level of 10% and then decreased.
8. As the replacement level of cement by silica fume increases there is an increase in split tensile strength & flexural strength for M30 grade of concrete up to 10% replacement level, and beyond that level there is a decrease in split tensile and flexural strength.
9. Using 10% silica fume with 0.3% fiber percentage the 28 days compressive strength increases 11% more than concrete with 0.3% fiber only.
10. So it is inculcated that 0.3% Recron fibre and replacement of 10 % silica fume with cement is required to achieve desired needs.
