Abstract- The world has observed a large scale destruction due to frequent earthquakes, resulting in loss of mane lives and imparting failure of structures. It is the need of the hour to offer utmost attention to the adequacy of structures, specially RC framed structure keeping seismic situation into consideration. To represent the same, in this project a Fifty year old, fourstorey building is taken as the base of this study. The structure is constructed in Zone II as specified in IS 893:2000. The non structural members are considered to be infilled with brick masonary.

The structure considered for this study has been modeled in STAAAD.Pro V8i taking into conisideration M15 grade concrete and Fe 250 grade steel. The structure is designed once without considering seismic loading and also considering seismic loading. The resulting moments and shear forces have been opted from the software analysis and thean a comparative study has been undergone with the capacity of the considered structure.

The most efficient method of retrofitting, FRP jacketing, is then applied of the failing members of considered 4-storey framed structure. For design of retro fittings, the specifications prescribed in ACI 440 2R.02 have been followed. The same code is used in the design calculations. Not only Serviceability checks but also creep rupture limit check are performed for the FRP strengthening system, as the structure is designed based on Limit State Method.

The only limitation involved with this thesis is that the code does not provide a specific method for the design of columns

I. INTRODUCTION

India is segmented into four seismic zones, Zone II, Zone III, Zone IV and Zone V, based on Indian Standard 1893:2002. Different zone factors are assigned to respective zones mentioned above, based on intensity of earth quake and importance factors associated with it. Importance factor can be defined as a factor used to get the plan seismic power contingent upon the practical utilization of the construction, portrayed by hazardous consequences of its failure, its postseismic tremor useful need, notable worth, or on the other

Page | 224

hand financial significance. On the other hand, intensity of earthquake is defined as "The intensity of an earthquake at a spot is a measure of the strength of shaking during the earthquake, and is demonstrated by a number as indicated by the adjusted Mercalli Scale or M.S.K. Size of seismic powers". Based on IS 1893:2002, the sieimic intensities of various zones are indicated below, with reference to mentiond IS code.

Table 2 Zone Factor, Z

(Crause 0,4.2)							
Seismic Zone	П	ш	IV	v			
Seismic Intensity	Low	Moderate	Severe	Very Severe			
Ζ	0.10	0.16	0.24	0.36			

A 4-storey building is considered for the study in this project. The building is designed and analysed as Ordinary Moment Resisting Frame (OMRF), located in zone II (as prescribed in IS 1893:2002), having seismic intensity 0.10. The existing structure is considered to be at-least fifty years old and is not designed for resisting earthquake or seismic shakes. Since, the existing structure is not designed to resist seismic forces, it may fail when subjected to moderate or strong earthquake. On carrying out the seismic analysis of existing structure, it was found vulnerable to earthquakes and suitable retrofitting methods are suggested on priority basis.

FOURTH STOREY

To make any existing framed structure perform better under seismic situations, seismic retrofitting is the best and most popular method. Seismic retrofitting can be described as the procedure of modifying any existing framed structure, to make them less prone to failure under seismic situations. This resistance for earthquakes can be attained easily by following following mentioned practices-

- By reducing the seismic demands on members and the structures as a whole
- By increasing the member capacities

For performing the seismic analysis, an existing fourstorey building is been considered. The existing structures consist of eight bays (rooms) spanning 3.5 meters . A projected slab cantilevered for 1.2 meters is provided in the structure. Floor height of existing structure is considered as 3.3 meters (clear span).

The structure is situated in Seismic Zone II, as specified in IS 1893:2002 Seismic zones classifications, which has the seismic intensity of 0.10. The structure is considered as Ordinary Moment Resisting Frame (OMRF). Also, the structure is built on medium soil.

The structure is then analyzed under seismic loading and the failing members are then retrofit using FRP Jacketing. The method of analysis used in the project is Equivalent Static Method. The initial part of analysis to determine the members that fail under earthquake loading is done by calculating the Demand- Capacity Ratio (DCR) for each member individually. Determining which members will fail is essential because it gives a rough idea about which retrofit technique to proceed with- global or local. The detailed evaluation of the building involves equivalent static lateral force procedure, load with response reduction factors and Demand Capacity Ratio (DCR) for ductility as in IS 13920:1993. Since the building dates back to a period 50 years early, the grade of concrete is assumed to be M15 and for steel Fe250.

Checks done:

- 1. DCR for moments of resistance in sagging and hogging for beams
- 2. DCR for shear capacity in beams
- 3. DCR for moment of resistance in columns
- 4. DCR for shear capacity in columns

Demand stands for the forces or loads applied to the structural element under seismic loading.

Capacity of the structural element can be defined as permissible strength of the same

DCR= Demand/Capacity

The member is said to be passing if the demand to capacity ratio does not exceeds unity (one).

Conversely, The member is said to be failed if the demand to capacity ratio exceeds unity (one).

The demand to capacity ratio is proved to be an important and key feature in determining whether the structural element is passed or failed under given loading exposure. In this project, flexure and shear checks are performed for all the structural members for which demand to capacity ratio is exceeding unity (ONE).

II. RESULTS AND OBSERVATIOBS

Moment Capacity of Beams

III. CONCLUSION

The analysis of beams by Equivalent Static Method revealed that most of the beams failed in flexural capacity. The number of failing beams decreased with increasing storeys. However, the number of beams failing in shear capacity were very less i.e. beams 23, 36, 40 in 1st storey; 112, 116, 118 in 2nd storey; 188, 192 in 3rd storey.

Based on the above observations, the immediate need to counter deficiency in flexural capacity was identified and the FRP jacketing scheme was suggested only for beams, failing in flexure. Due to the high tensile strength and stiffness, stability under high temperatures and resistance to acidic/alkali/organic environments, carbon fiber was chosen as the FRP material to be used.FRP strips that are commercially available are not made to a universal standard but a localized standard as set by the manufacturing company. Thus, the dimensions considered for the strips were strictly as per a design example in ACI 440.2R-02. The code states though, that wider and thinner FRP strips have lower bond stresses and hence, provide higher level of strength. The FRP design method used in this project is essentially trial and error where the value of the depth of neutral axis has to be assumed and compared with the value obtained. Thus, efforts were made so that the number of plies to be applied to a continuous series of beams, say in the longitudinal or transverse direction, would remain the same. This would ensure feasibility of application of the FRP system to the beams.
